IHC

TEST DESCRIPTION	RESULT	UNITS	BIOLOGICAL REFERENCE RANGE

TEST NAME

IMMUNOHISTOCHEMISTRY ER (EP1) PgR (EP2) Her-2/neu (EP3) Ki-67(MIB1).

SPECIMEN INFORMATION

Received 02 paraffin blocks and 02 stained slides labelled as 5744/26 A,B.

CLINICAL HISTORY

Suggestive of infiltrating ductal carcinoma of right breast.

METHETOLOGY

Immunohistochemisty

IMMUNOHISTOCHEMICAL INTERPRETATION

MARKERS (CLONES)	RESULTS	INTERPRETATION
Estrogen receptor (ER) (SP1)	0% of cells with no nuclear staining in the invasive component of the tumour. Proportion score: 0, Intensity score: 0 (Allred Score: 0)	Negative
Progesterone receptor (PR) (SP2)	0% of cells with no nuclear staining in the invasive component of the tumour. Proportion score: 0, Intensity score: 0 (Allred Score: 0)	Negative
HER2/ErbB2 (SP3)	No staining observed (Score 0)	Negative
KI 67	No staining observed (Score 0)	Negative

IMPRESSION

paraffin block for immunohistochemistry ER, PR and HER2/ErbB2:

- **Estrogen receptor (ER): Negative (Allred Score: 0)**
- **Progesterone receptor (PR): Negative (Allred Score: 0)**
- **HER2/ErbB2: Negative (Score 0).**
- **KI 67 :Negative (Score 0)**

COMMENTS

All immunohistochemistry markers have been evaluated in the context of appropriate positive and negative controls. A result is considered uninterpretable as a result of the type of fixative used (non 10% neutral buffered formalin), time to fixation (> 1 hour), duration of fixation (> 6 hr or <72 hour), strong decalcification, or inappropriate staining of normal internal or external assay controls. An alternative sample for retesting is then usually recommended. These assays

have not been validated on decalcified specimens.

LP-PLA2

TEST DESCRIPTION	RESULT	UNITS	BIOLOGICAL REFERENCE RANGE
LP-PLA2	115.9	U/L	0.0 - 225.0

Method: PHOTOMETRY

Clinical Significance

Lp-PLA2 is an inflammatory protein that is produced in the vascular intima and is more abundant in advanced Atherosclerotic lesions than in early-stage lesions. As a result, its measurement could aid in the identification of patients with rupture-prone plaques. Lp-PLA2 has much less variability than hsCRP and is not elevated in systemic inflammatory conditions. It appears to be a more specific vascular inflammation marker. Elevated baseline Lp-PLA2 levels have been linked to an increased risk of cardiovascular disease (CVD) events. Even after adjusting for CVD risk factors, the risk prediction remains significant.

RA,ASO,CRP

TEST DESCRIPTION	RESULT	UNITS	BIOLOGICAL REFERENCE RANGE
RHEUMATOID FACTOR, RA Method: Nephelometry	6.9	IU/mL	0.0 - 18.0
Antistreptolysin-0 (ASO) Method: Immunoturbidimetry	75.8	IU/mL	1 - 200
CRP Method: Immunoturbidimetry	1.7	mg/L	0.0 - 5.0

.

The test detects rheumatoid factor (RF) in your blood. This protein is part of a normal immunogenic response to the presence of a foreign entity, such as bacteria or a virus, forming a complex that the immune system can remove.

Antistreptolysin O (ASO) is an antibody targeted against streptolysin O, a toxic enzyme produced by group A *Streptococcus* bacteria. ASO and anti-DNase B are the most common of several antibodies that are produced by the body's immune system in response to a strep infection with group A *Streptococcus*. This test measures the amount of ASO in the blood.

A c-reactive protein test measures the level of c-reactive protein (CRP) in a sample of your blood. CRP is a protein that your liver makes. Normally, you have low levels of c-reactive protein in your blood. Your liver releases more CRP into your bloodstream if you have inflammation in your body. High levels of CRP may mean you have a serious health condition that causes inflammation.

TEST DESCRIPTION	RESULT	UNITS	BIOLOGICAL REFERENCE RANGE
TYPHI DOT IgG Method: RAPID	NEGATIVE	.	- - -
TYPHI DOT IgM Method: RAPID	POSITIVE	.	- - -

.

Typhoid IgG and IgM tests are blood tests used to diagnose typhoid fever. IgG and IgM are types of antibodies produced by the immune system in response to an infection. IgM antibodies are produced first, followed by IgG antibodies. The presence of these antibodies in the blood indicates that the body has been exposed to the Salmonella typhi bacteria.

Typhoid IgM Test

The typhoid IgM test is used to detect the presence of IgM antibodies in the blood. IgM antibodies are produced in the early stages of the infection, usually within 1-2 weeks after exposure to the bacteria. A positive result on the typhoid IgM test indicates that the individual is currently infected with the Salmonella typhi bacteria. The test is highly specific, meaning that it rarely gives false-positive results.

Typhoid IgG Test

The typhoid IgG test is used to detect the presence of IgG antibodies in the blood. IgG antibodies are produced in the later stages of the infection, usually after 2-3 weeks. A positive result on the typhoid IgG test indicates that the individual has been exposed to the Salmonella typhi bacteria in the past and has developed immunity against it. The test is less specific than the typhoid IgM test, meaning that it can sometimes give false-positive results

VDRL TITER 1:32 Method: -	NON REACTIVE	-	- - -
VDRL TITER 1:64 Method: -	NON REACTIVE	-	- - -

INTERPRETATION

Titres of ≥1: 8 and rising Titres are significant. 2. Titres are reported only in reactive cases. 3. Positive result indicates ongoing or recent infection and the diagnosis should be confirmed by specific Treponemal tests such as TPHA & FTA- Abs. 4. The reactivity will vary with Primary (60-86%), Secondary (99%) and Tertiary (98%) stage of Syphilis. 5. False positive results may be observed in patients of Malaria, Hepatitis, Mumps, Leprosy, and Infectious Mononucleosis, Rheumatoid Arthritis and Collagen disease. 6. False negative reaction may be due to processing of sample collected early in the course of disease, Immunosuppression and due to prozone effect. 7. Test conducted on serum. Uses ? To screen for presence of Syphilis infection. ? To monitor the progression of disease. ? To assess the response to therapy (decreasing Titres) in patients being treated for Syphilis.
